Fluorescence in situ hybridization (FISH) technique was employed to study the expression of messenger ribonucleic acids (mRNAs) in the human and pig inner ear. The specific fluorescent probes used in this study detected beta-actin, fibronectin, connexin-26, and myosin heavy chain-1 (MHC-1) mRNAs. The FISH protocol followed was designed to maximize the fluorescence produced by the probes. FISH results indicated that the human and porcine inner ears have a different pattern of expression for beta-actin mRNA. The finding that the actin and fibronectin mRNAs of human inner ears are not found in the pig inner ear suggests that these two mRNAs may play a role in the process of otoconial differentiation. The expression pattern of connexin-26 mRNA of the human and pig inner ears was similar to that of beta-actin mRNA. The possible function of this gene in the inner ear remains unclear. The expression pattern of MHC-1 mRNA of the human and porcine inner ears was found to be similar to the distribution of the actin and fibronectin mRNAs in the human inner ear.Q: How to know the order of a unique index in SQL Server?
